

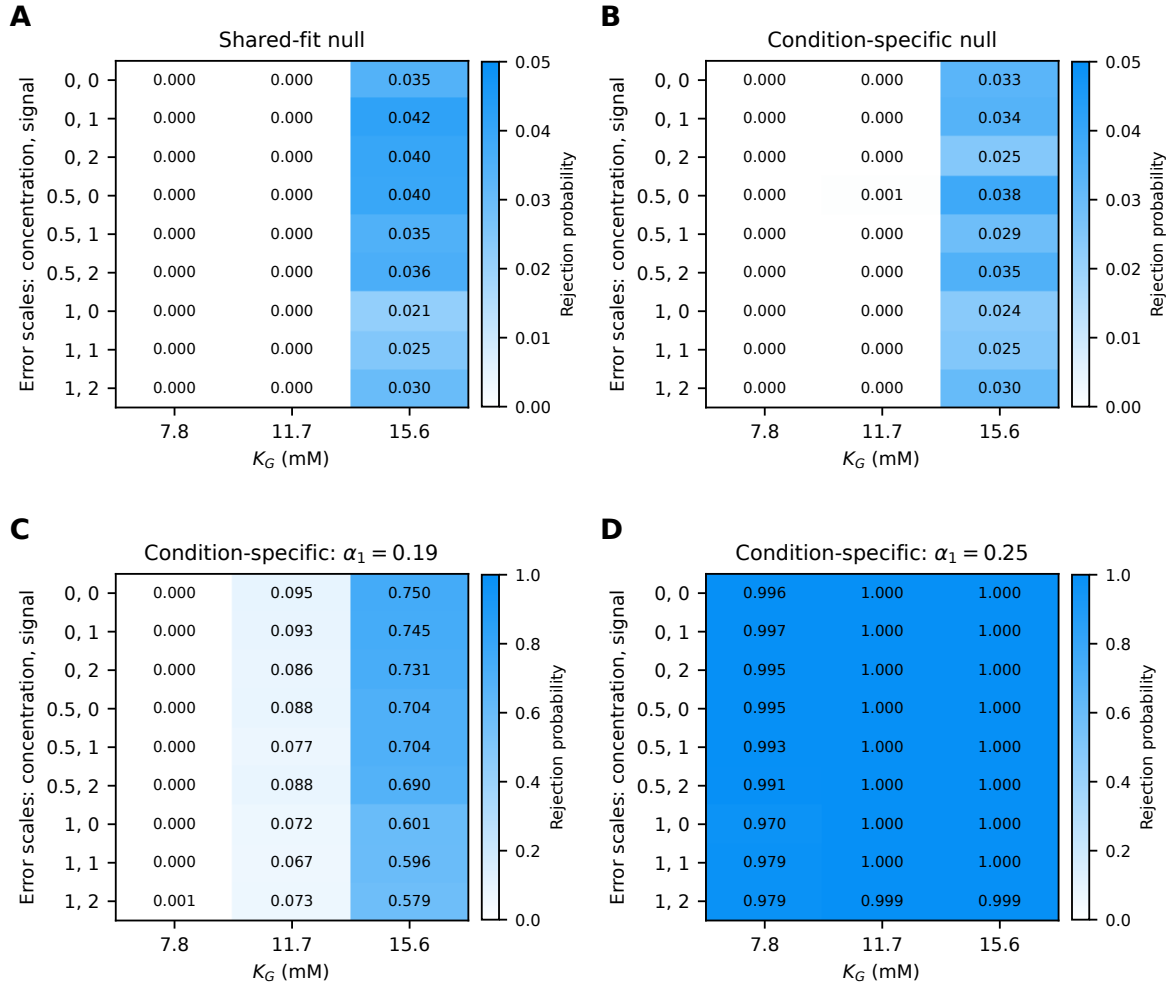

Figure S9: **All audited nuisance cells for the null and two alternative effects.** Each cell gives the rejection proportion from 2,000 independently evaluated trials after separate parametric calibration. Rows cross concentration-error scales $c = 0, 0.5, 1$ with signal-error scales $s = 0, 1, 2$; their physical error magnitudes are defined in S3 Appendix E5. (A–B) Shared and condition-specific fits under the $\alpha_1 = 0.17$ reference. (C–D) Condition-specific fits under $\alpha_1 = 0.19$ and 0.25 . Null panels use a 0–0.05 color scale; alternative panels use 0–1. Printed values are rounded to three decimal places. These are a discrete sensitivity grid, not an interpolated continuous performance guarantee.
